So in terms of our general notation, we have $x(t) = (w(t), q(t))^T$ and $x_0 = (w_0, q_0)^T$. We are taking the running payoff to be $r \equiv 0$, and the terminal payoff $g(w, q) = q$. The answer will again turn out to be a bang-bang control, as we will explain later. **EXAMPLE**

This textbook presents, in a mathematically precise manner, a unified introduction to deterministic control theory. With the exception of a few more advanced concepts required for the final part of the book, the presentation requires only a knowledge of basic facts from linear algebra, differential equations, and calculus.

Combining a mathematical model with multiple datasets, we found that the median daily R_t of SARS-CoV-2 in Wuhan probably varied between 1.6 and 2.6 in January, 2020, before travel restrictions were introduced. We also estimated that transmission declined by around half in the 2 weeks spanning the introduction of restrictions.
